

COOPER PRECISION REVERSION PROTOCOL

Official Rulebook — Update & Changelog to Version 1.4

10 August 2026 | Author / Founder: Raymon Michael Cooper

1. PURPOSE OF THIS UPDATE

Live observation during live sessions showed that the 5-minute + 1-minute pair frequently produced excessive noise: RSI(14) on the 1-minute chart continuously broke overbought/oversold territory, price action tracked RSI closely, and the market frequently printed new session extremes without respecting prior range boundaries. Higher timeframe pairs (15m/5m and 30m/15m) produced clearer RSI-to-price relationships and higher-quality mean-reversion signals. This update formalizes the shift to higher working pairs, removes 5m+1m from the approved set, and clarifies RSI usage rules so the strategy remains true to its range-bound mean-reversion edge while reducing false triggers.

2. REVISED CHART PAIR STRUCTURE (Section replacement)

Approved working pairs and recommended usage are as follows:

Primary Working Pairs (Approved)

- **15-minute (Structure) + 5-minute (Execution)** — Default for most sessions. Provides cleaner RSI behavior, better range definition, and still-responsive entry timing.
- **30-minute (Structure) + 15-minute (Execution)** — Preferred when ranges are larger, slower, or volume is lighter. Highest quality S/R levels and least noise.

Removed from approved pairs

- **5-minute (Structure) + 1-minute (Execution)** — No longer an approved working pair. Do not use for structure or execution under this Protocol. When conditions feel tight or noisy, remain on the 15m+5m pair rather than stepping down.

Selection continues to be guided by time of day, volume, and current range size. The static 1-Hour (or 4-Hour) chart remains mandatory in a separate window for long-term trend context and never generates entries.

3. RSI USAGE CLARIFICATION (New / Expanded Guidance)

RSI is one of four confirmation tools (alongside volume, price action, and the S/R level itself). Its reliability is timeframe-dependent:

On the 5-minute execution chart:

- Absolute overbought (>70) / oversold (<30) levels are frequently violated and carry low standalone reliability as mandatory entry conditions.
- Prefer RSI divergence at the actual Support or Resistance level (price makes a new extreme while RSI fails to confirm).

On the 15-minute and 30-minute charts:

- RSI extremes are significantly clearer and more meaningful.
- When RSI reaches an extreme while price is still mid-range, treat the reading as an alert / preparation signal only. Do not enter. Wait for price to actually reach a confirmed range boundary plus supporting price action and volume.

Optional technical adjustment: a faster RSI period (7 or 9) may be displayed on the execution chart purely as a visual aid for divergence. The structure chart should retain the standard 14-period RSI.

4. OPERATING EMPHASIS (Reinforced)

- When price is making new session lows or highs and tracking RSI closely on lower timeframes, the market is likely in a momentum or expanding-range environment. Respect the existing pause rule: after a confirmed range break, pause 30 minutes or until a new clear range forms on the higher structure chart.
- Quality over frequency. Higher working pairs will reduce trade count but improve the probability that levels are respected. This is the correct trade-off for CPRP.
- Hard risk limits (–\$50 to –\$100), instrument restriction (MES primary, MNQ, MYM only), and the static higher-timeframe context window remain unchanged.

5. VERSION CONTROL

Base document: Cooper_Precision_Reversion_Protocol_Official_Rulebook_v1.3.pdf (9 August 2026)

This update: Version 1.4 — Chart Pair Hierarchy & RSI Clarification (10 August 2026; 5m+1m removed from approved pairs)
