Raymon Michael Cooper

Platforms: Ironbeam + NinjaTrader (Web preferred)

CHANGE LOG — v1.4 (Aug 14, 2026)

UPDATED: Execution timeframe selection is now adaptive between the **1-minute** and **5-minute** charts. Select the chart that is actively **respecting RSI levels** — i.e., price is bouncing down at RSI Overbought and bouncing up at RSI Oversold. This replaces the previous fixed lower-TF pairing for entry precision.

1. CORE PHILOSOPHY & OBJECTIVE

The Cooper Precision Reversion Protocol (CPRP) is a disciplined, rules-based mean-reversion scalping system designed for micro equity-index futures. It capitalizes on high-probability reversals inside confirmed Support/Resistance (S/R) ranges — whether the range is sideways or a trending channel. Direction of the overall trend does not matter; the protocol fades extremes at the boundaries of the active range.

Primary edge comes from combining clean S/R structure with RSI respect on the selected lower timeframe. Trades are only taken when price action, volume, and RSI alignment confirm a rejection of the extreme. The system prioritizes capital preservation through tight, hard-defined risk and micro-contract sizing.

2. INSTRUMENTS

- **MES** (Micro E-mini S&P; 500) — Primary instrument
- **MNQ** (Micro E-mini Nasdaq-100)
- **MYM** (Micro E-mini Dow)

Only these three micro contracts are permitted. Full-size or other products are outside the protocol. Micros keep risk tightly controlled and allow consistent execution of the hard-dollar risk rule.

3. CHART SETUP & TIMEFRAME SELECTION (UPDATED v1.4)

3.1 Context Chart (Always Present)

Keep a static **1-Hour chart** (or 4-Hour alternative) open in a separate window at all times. This chart provides higher-timeframe trend context and major S/R levels only. **It does not generate entries.**

3.2 Range Identification Charts

Higher timeframes (15m, 30m, or combinations previously used) continue to be used to define and confirm the active Support/Resistance range or channel. Selection of the higher TF remains driven by time of day, volume profile, and the size/clarity of the range.

3.3 Execution / Scalping Chart — Adaptive 1m or 5m (NEW RULE)

For precise entry timing and confirmation, use either the **1-minute** or the **5-minute** chart — whichever is currently **respecting RSI levels**.

Definition of “Respecting RSI Levels”:

- Price is **bouncing down** (rejecting) when RSI reaches or exceeds the Overbought zone (typically ≥ 70).
- Price is **bouncing up** (rejecting) when RSI reaches or falls to the Oversold zone (typically ≤ 30).

Observe both the 1m and 5m charts. Choose the one that is showing cleaner, more consistent reversals at the RSI extremes in the current session or range. If neither is respecting the levels, stand aside or wait for clearer structure. Do not force trades on a chart that is ignoring RSI extremes.

This adaptive selection improves signal quality by aligning the entry timeframe with the market's current responsiveness to momentum extremes, reducing false breakouts and improving the probability of successful mean-reversion within the defined S/R range.

4. ENTRY RULES

Trade only inside a **confirmed Support/Resistance range** (sideways consolidation or trending channel). Direction of the larger trend is irrelevant — the protocol sells resistance and buys support.

Long Entry (Buy Support)

1. Price approaches or tags a confirmed Support level.
2. On the selected execution chart (1m or 5m that respects RSI), RSI is Oversold or approaching Oversold.
3. Price action shows rejection / bounce (wick, engulfing, pin bar, or clear reversal candle).
4. Volume confirmation preferred (increased volume on the bounce or absorption).
5. Enter long on confirmation of the bounce.

Short Entry (Sell Resistance)

1. Price approaches or tags a confirmed Resistance level.
2. On the selected execution chart (1m or 5m that respects RSI), RSI is Overbought or approaching Overbought.
3. Price action shows rejection / bounce down.
4. Volume confirmation preferred.
5. Enter short on confirmation of the rejection.

All four elements — S/R location, RSI condition on the chosen TF, price-action rejection, and (ideally) volume — should align. Missing multiple confirmations = no trade.

5. RISK MANAGEMENT & EXITS

Hard Risk Rule: Exit any trade at a maximum loss of **–\$50 to –\$100** (account for commissions/slippage). This is non-negotiable. No averaging down, no “hope” holds.

Targets: Prefer the opposite side of the defined range or a logical intermediate level. Partial profits or trailing stops may be used once the trade is in profit, but the hard stop remains the primary risk control.

If the active S/R range is clearly broken (decisive close beyond the level with volume), **pause trading for 30 minutes** or until a new, clean range forms. Do not chase the breakout.

6. OPERATIONAL RULES & DISCIPLINE

- Trade only during liquid hours when the chosen 1m/5m chart is providing clean RSI respect.
- Prefer NinjaTrader web charts for clear High/Low display.
- Maintain the static 1H (or 4H) context window at all times.
- Journal every trade: TF selected (1m or 5m), RSI reading, S/R level, entry reason, outcome.
- No trading when neither 1m nor 5m is respecting RSI extremes — patience is part of the edge.
- Session goal is precision and consistency, not maximum trade count.

This document supersedes all prior versions. Version 1.4 incorporates the adaptive 1-minute / 5-minute RSI-respect selection rule effective immediately.
